Date: 29 April 2020. Commonly found in small molecule drugs, the humble methyl group can have a dramatic effect on binding. A seemingly mundane change from C-H to C-Me can improve IC 50 values by orders of magnitude. In addition methylation can have a favourable effect on solubility, off-target selectivity and has been used to introduce a 'metabolic hotspot' for shortening a product's half-life.

Date: 26 August 2020. The cyclopropane ring is now part of the established molecular architecture used in drug discovery and development with a proven track record in marketed small molecule drugs. In total 18 NCE's containing a cyclopropyl group were approved over the past decade. There are several reasons this small ring system is attractive to drug hunters, including coplanarity of the ring atoms, shorter C-C bonds with enhanced p-character, and shorter C-H bonds ...

Abstract: Mammalian carboxylesterases are key serine hydrolases that catalyze the hydrolysis of a wide variety of ester compounds including corresponding carboxylic acids and alcohols. In human, two major carboxylesterases, CES1 and CES2, have been identified and characterized over the past decade. CES1 inhibitors have potential applications in the treatment of hypertriglyceridaemia, obesity and type 2 diabetes. It is thought that this enzyme plays prominent role in the metabolism of cholesteryl esters.
