Regulation of Translation In Eukaryotes Translational regulation refers to the control of the levels of protein synthesized from its mRNA. In eukaryotes, regulation of protein synthesis can occur by modification of DNA or at the level of transcription within the nucleus, processing of mRNA in the nucleus, or translation in the cytoplasm.

Regulation of Translation In Eukaryotes | Molecular ...

Translation regulation typically targets initiation. It may be global, affecting the synthesis of many polypeptides at once, or specific, affecting a single polypeptide. Global regulation involves changes in the activity of eukaryotic initiation factors (eIFs) that would typically affect all cellular protein synthesis.

*regulation, translational control of existing mRNAs allows for more rapid changes in cellular concentrations of the encoded proteins and, thus, can be used for maintaining homeostasis in addition to modulating more permanent changes in cell physiology or fate. The process of translation can be divided into initi-*

*Regulation of Translation Initiation in Eukaryotes ...*

*Translation occurs in the cytoplasm where the ribosomes are located. Ribosomes are made of a small and large subunit which surrounds the mRNA. In eukaryotic translation 80S ribosomes with 40S and 60S subunits are used. The mRNA is synthesized from DNA only. In eukaryotes, there is single initiation and termination site. 2. Template:*

*Translation in Eukaryotes | Genetics*

*Translation (Protein Synthesis) in Eukaryotes. Translation involves translating the sequence of a messenger RNA (mRNA) molecule to a sequence of amino acids during protein synthesis. It is the process in which ribosomes in the cytoplasm or ER synthesize proteins after the process of transcription of DNA to RNA. The Ribosomes*

*Translation regulation by miRNAs: Sequence specific Repress translation at 3' UTR Can act in conjunction with RNA binding protein Almost 21 nucleotide Degree of repression increases with the increasing number of miRNA Repression efficiency might also be influenced by the distance and sequence between miRNA target sites and also their position in the 3' UTR In some cases miRNA act as a adaptor for sequence specific RNA binding protein.*

*eukaryotic translation initiation and its regulation*

*These developments have provided a solid foundation for studying the regulation of translation initiation by mechanisms that include the modulation of initiation factor activity (which affects almost all scanning-dependent initiation) and through sequence-specific RNA-binding proteins and microRNAs (which affect individual mRNAs).*

*The Mechanism of Eukaryotic Translation Initiation and ...*

*Gene expression is primarily regulated at the pre-transcriptional level, but there are a number of mechanisms for regulation of translation as well. One well-studied animal system is the iron-sensitive RNA-binding protein, which regulates the expression of genes involved in regulating intracellular levels of iron ions.*

*10.8: Regulation of Translation - Biology LibreTexts*

*Eukaryotic Translational and Post-Translational Regulation After the RNA has been transported to the cytoplasm, it is translated into protein. Control of this process is largely dependent on the RNA molecule. As previously discussed, the stability of the RNA will have a large impact on its translation into a protein.*

*Eukaryotic Translational and Post-Translational Regulation ...*

*Eukaryotic gene expression is more complex than prokaryotic gene expression because the processes of transcription and translation are physically separated. Unlike prokaryotic cells, eukaryotic cells can regulate gene expression at many different levels. Eukaryotic gene expression begins with control of access to the DNA.*

*Eukaryotic Gene Regulation | Biology for Majors I*

*Eukaryotic translation is the biological process by which messenger RNA is translated into proteins in eukaryotes. It consists of four phases: initiation, elongation, termination, and recycling.*

### *Eukaryotic translation - Wikipedia*

*Abstract. There is no doubt about the importance of transcriptional control for eukaryotic gene expression. Modern approaches of reversed genetics, involving analysis of the expression of eukaryotic gene sequences contained in plasmid vectors upon their introduction into eukaryotic cells, have provided a powerful and convenient tool to dissect this manner of control.*

### *Regulation of Eukaryotic Translation | SpringerLink*

*Translation in prokaryotes is usually regulated by blocking access to the initiation site. This is accomplished via base-paired structures (within the mRNA itself, or between the mRNA and a small trans-acting RNA) or via mRNA-binding proteins. Classic examples of each mechanism are described.*

### *Regulation of translation via mRNA structure in ...*

*Translational regulation refers to the control of the levels of protein synthesized from its mRNA. This regulation is vastly important to the cellular response to stressors, growth cues, and differentiation.*

### *Translational regulation - Wikipedia*

*Eukaryotic Translation The broad outlines of eukaryotic protein synthesis are the same as in prokaryotic protein synthesis. The genetic code is generally the same (some microorganisms and eukaryotic mitochondria use slightly different codons), rRNA and protein sequences are recognizably similar, and the same set of amino acids is used in all organisms.*

### *Eukaryotic Translation*

*Like transcription, translation is controlled by proteins that bind and initiate the process. In translation, the complex that assembles to start the process is referred to as the translation initiation complex. In eukaryotes, translation is initiated by binding the initiating met-tRNA<sub>i</sub>*

to the 40S ribosome.
